

# Triangulation

## Triangulating Monotone Polygons

### - Analysis

Junhui DENG

[deng@tsinghua.edu.cn](mailto:deng@tsinghua.edu.cn)

## Correctness

- ❖ First, the SCC is maintained during the **entire** algorithm run
- ❖ Besides,
  - each time a triangle is chopped off,
  - more properties are satisfied that
  - the chopping diagonals
    - can't **be blocked by** any edge; and
    - can't **block** or **be blocked by** any of the old diagonals
- ❖ Therefore we have that
  - all diagonals generated by the algorithm are **internal** ones

## Complexity

❖ Note that

- (with both chains sorted already)  
all vertices can be sorted in  $\mathcal{O}(n)$  time;
- each vertex is pushed into  $S$  at most **twice**  
(once as  $c$  and the other time as  $t$ ); and
- altogether  $n - 2$  triangles are chopped off and  
each costs  $\mathcal{O}(1)$  time

❖ We can now conclude that

a monotone polygon with  $n$  vertices

can be triangulated in  $\mathcal{O}(n)$  time
