

# Point Location

Performance Of Trapezoidal Map

- Query Time

Junhui DENG

## Search Length

❖ Since  $q$  could fall thru

up to 3 levels in  $SS(S)$

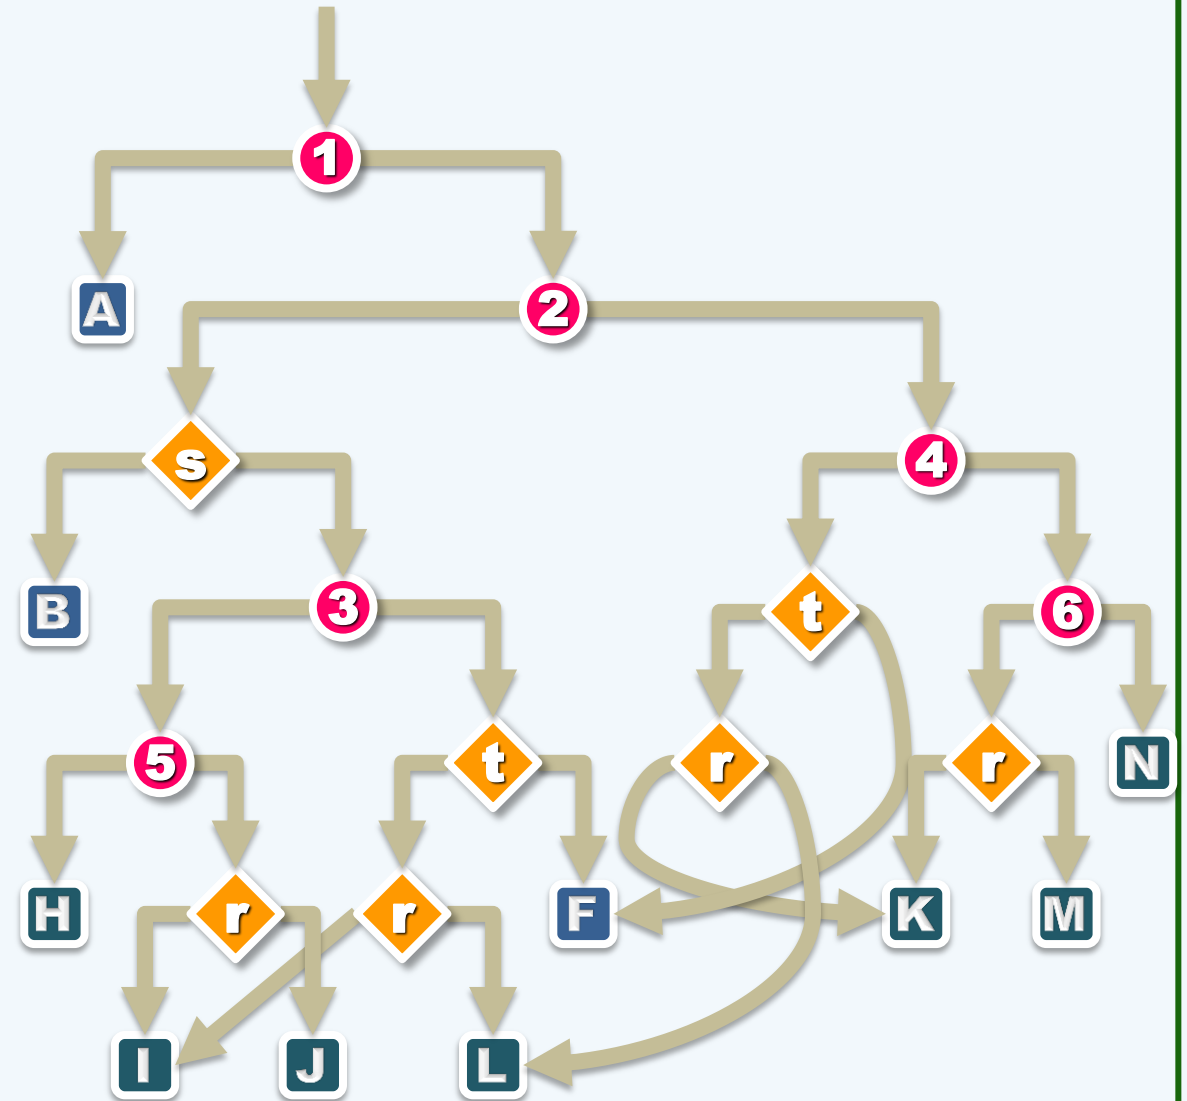

as a result of the insertion,

the expected length of

the search path of  $q$  in  $SS(S)$

is at most:

$$3 \times (P_1 + P_2 + \dots + P_n)$$

$$E[ \text{ Query Time } ] = \mathcal{O}(\log n)$$

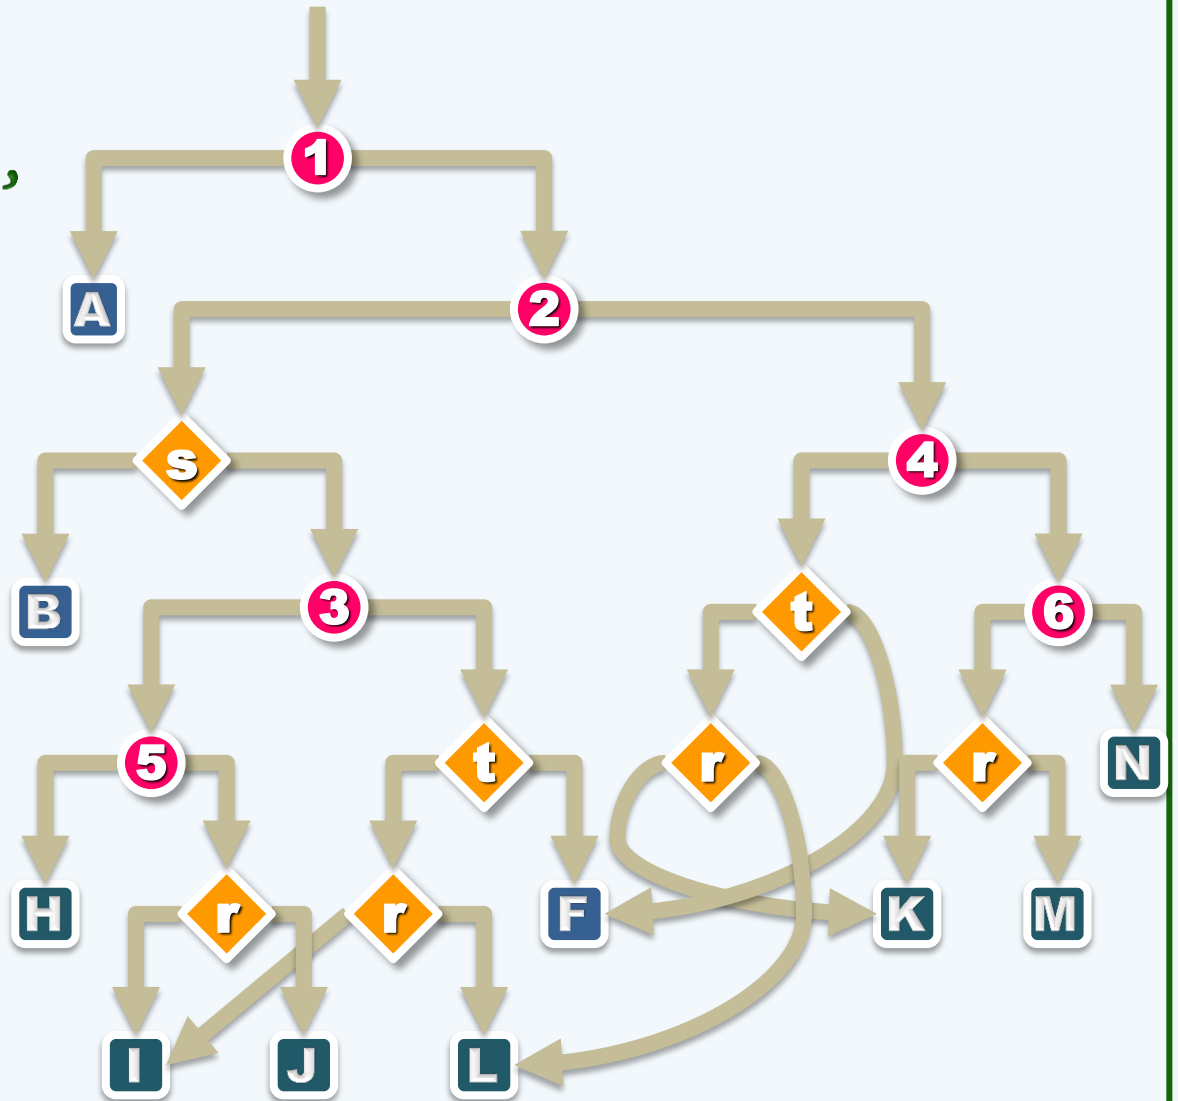

❖ Using **backward analysis** once again,

we can prove that  $P_k \leq 4/k$

❖ Hence, the expected length

$$\leq 3 \times ( 4/1 + 4/2 + \dots + 4/n )$$

$$= 12 \times \Theta(\ln n) = \mathcal{O}(\log n)$$

## Any Way, Time For a Conclusion

- ❖ Given a set of  $n$  non-crossing line segments in the plane,
  - in  $\text{expected-}\mathcal{O}(n \log n)$  time, it is possible to construct a search structure
  - of size  $\text{expected-}\mathcal{O}(n)$
  - that answers point location queries in  $\text{expected-}\mathcal{O}(\log n)$
- ❖ It's worthy to mention again that the expectations here are taken over all  $\text{permutations}$  of the input segments
- ❖ What does this mean in practice?
